# PROBLEM SET 5 Due on Friday, Apr 29.

Name: DAMONTE MARIA IRENE

Id: 192901

### Instructions:

- Make sure you are working on your problem set as each problem set is different.
- The answers to the questions of this problem set are to be given exclusively in the answer sheet
- The answers sheet MUST be printed and not photocopied. Photocopies will not be accepted.
- $\bullet$  Questions marked with the symbol  $\clubsuit$  admit more than one correct answer
- Please fill the boxes in the answer sheet completely using a black pen as follows

Question 1: B C D E

- The answer sheet must not be creased or folded otherwise your problem set won't be graded.
- You can hand back your problem set at the END of class on Friday, April 29th.

With a sample of 706 observations, we estimate the following model:

$$ln(hwage_i) = \beta_0 + \beta_1 age_i + \beta_2 age_i^2 + \beta_3 educ_i + \beta_4 yngkid_i + u_i$$

and obtain these results:

where *lhwage* is the logarithm of the hourly wage in euro, *age* is measured in years, *educ* is years of education and yngkid is a variable equal to 1 in case the person has a child younger than three years. **Question 1** What is the interpretation of  $\beta_1$ ?

- A Increasing age by one year, the hourly wage increases by 0.071 euros on average, ceteris paribus.
- B Increasing age by one year, the hourly wage increases by 7.1% on average, ceteris paribus.
- C By itself does not have a proper interpretation.
- D Increasing age by one year and keeping its square fixed, the hourly wage increases by 7.1% on average, ceteris paribus.

### **Question 2** What is the interpretation of $\beta_3$ ?

- An increase of 1% in education is associated with a change of about 7% euros in hourly wage, on average, ceteris paribus.
- B One year more of education is associated with a change of about 0.07 euros in hourly wage, on average, ceteris paribus.
- C One year more of education is associated with a change of about 0.0007 in hourly wage, on average, ceteris paribus.
- D One year more of education is associated with a change of about 7% in hourly wage, on average, ceteris paribus.
- E An increase of 1% in education is associated with a change of about 0.07 euros in hourly wage, on average, ceteris paribus.
- F One year more of education is associated with a change of about 0.07% in hourly wage, on average, ceteris paribus.

**Question 3** What are we testing when we check whether  $\beta_2$  is significant?

- A We check whether the logarithm of hourly wage depends on age.
- B We check whether the logarithm of hourly wage depends negatively on age.
- C We check whether the logarithm of hourly wage depends linearly on age.
- D We check whether the logarithm of hourly wage depends positively on age.

**Question 4**  $\clubsuit$  Is  $\beta_3$  statistically higher than 0.05 at 5%?

- A Yes, it is, since the t-value is smaller than 1.64.
- B No, it is not, since the t-value is smaller than 1.96.
- C Yes, it is, since the t-value is larger than 1.64.
- D No, it is not since the t-value is larger than 1.96.
- |E| None of these answers are correct.

Question 5 Using a subset of the variables in the previous model, we would like to write a new one such that we obtain the elasticity of the hourly wage to education, and that, given in increase of one year in age, it returns a change in hourly wage in percent points. Choose the correct model among these:

$$\boxed{\mathbf{B}} \ ln(hwage_i) = \beta_0 + \beta_1 ln(age_i) + \beta_2 educ_i + u_i$$

$$\boxed{C}$$
  $ln(hwage_i) = \beta_0 + \beta_1 age + ln(\beta_2 educ_i) + u_i$ 

$$\boxed{D} ln(hwage_i) = \beta_0 + \beta_1 age_i + \beta_2 ln(educ_i) + u_i$$

$$\boxed{\mathrm{E}} hwage_i = \beta_0 + \beta_1 ln(age_i) + \beta_2 educ_i + u_i$$

**Question 6** Keeping other variables fixed, at what age the logarithm of hourly wage is maximized?

- At about 0, but this makes no sense.
- B At about 93.3 years.
- C At about 56.3 years.
- D At about 46.7 years.

Let us define with Y the amount of cholesterol in mlg in the blood and with Med a dummy variable which takes the value of 1 for medication B and 0 for medication A, where A and B are two different medications that lower cholesterol. Female is a dummy variable which takes the value of 1 for females and 0 otherwise.

Consider the following regression:

$$Y = \beta_0 + \beta_1 \times med + \beta_2 \times female + \beta_3 \times med \times female + u$$

Question 7 What is the average cholesterol value for women using medication A?

- $A \beta_0$
- B None of the others.
- $\bigcirc$   $\beta_0+\beta_2+\beta_3$
- $\square$   $\beta_2$
- $\begin{bmatrix} \mathbf{E} \end{bmatrix} \beta_0 + \beta_2$

Question 8 What is the effect of using medication B with respect to no medication for men?

- $A \beta_1$
- $\boxed{\mathbf{B}}$   $\beta_0 + \beta_1$
- C  $\beta_0$
- $D \beta_1 \beta_0$
- | E | None of the others.

These data are taken from the Medical Expenditure Panel Survey survey conducted in 1996. These data were provided by Professor Harvey Rosen of Princeton University and were used in his paper with Craig Perry "The Self-Employed Are Less Likely Than Wage-Earners to Have Health Insurance. So What?" in Douglas Holtz-Eakin and Harvey S. Rosen, eds., Entrepeneurship and Public Po licy, MIT Press 2004.

Among the variables in the dataset, ins is a dummy equal to one if the interviewee has the insurance; selfemp is equal to one if the interviewee is a self-employed workers; gender is equal to one if the in dividual is a male; married is one if the individual is married; health is one if the individual reports to be in good health; educ is 0 if the person has no education, 1 if he/she achieved middle school diploma, 2 for the high school diploma, 3 for the bachelor degree, 4 for the master degree and 5 for the PhD; age is in years and age2 is the square of age.

We estimate two models:

$$Pr(ins = 1|X) = \beta_0 + \beta_1 \times selfemp + \beta_2 \times married + \beta_3 \times gender + \beta_4 \times health + \beta_5 \times gender * health + \beta_6 \times educ + \beta_7 \times age + \beta_8 \times age^2$$

#### Coefficients:

	Estimate	Std.	Error	t	value	Pr(	> t	)
(Intercept)	0.297463	4 0	.058024	48	5.1	3 0.	0000	003
selfemp	-0.174236	1 0	.014174	40	-12.2	.9	< 2e	-16

education	0.226139	0.012852	17.60	< 2e-16
age	0.029150	0.009899	2.94	0.00323
age2	-0.000162	0.000126	-1.29	0.19821

**Question 9** What is the interretation of  $\beta_2$  in model (I)?

- A It does not have a proper interpretation.
- B On average, married individuals are 11.8% less likely than others to have an insurance, controlling for all other factors.
- C On average, married individuals are 11.8% more likely than others to have an insurance, controlling for all other factors.
- D On average, increasing married by one increases the probability to have an insurance of 11.8%, ceteris paribus.

### **Question 10** What is the interretation of $\beta_2$ in model (II)?

- A On average, married individuals are 45.5% more likely than others to have an insurance, controlling for all other factors.
- B It does not have a proper interpretation in terms of magnitude.
- C On average, a married worker has a probability of 45.5% to have an insurance, ceteris paribus.
- D On average, married individuals are 45.5% less likely than others to have an insurance, controlling for all other factors.
