## The Econometrics of DSGE Models

Giuseppe Ragusa Luiss University

**EIEF** 

Lecture 1: Introduction

April 1, 2014

## Outline of the course

- Motivation: DSGE models and their applications
- Approximating and solving DSGE models
  - State space representation
  - Onstructing log-linear approximation
  - 4 Higher order approximation techniques
- Frequentist estimation of DSGE models
- Bayesian estimation of DSGE models
- The twilight zone of DSGE estimation

## Course material

#### Textbook:

Canova, Fabio. Methods for applied macroeconomic research. Vol. 13. Princeton University Press, 2011.

## Papers:

An, Sungbae, and Frank Schorfheide. "Bayesian analysis of DSGE models." Econometric reviews 26.2-4 (2007): 113-172.

More papers will be introduced as we move along

#### Slides:

Will make them available @ www. gragusa. org/eief\_ dsge

## **Evaluation**

- **●** Final Test (50%) $\rightarrow$  Take home exam ==> applied
- 2 Problem sets (50%)
  - →Based on real world example (Matlab, R, Julia)
  - $\mapsto$  Assigned in class and due in one week

# DSGE quick history

Kydland, Finn E., and Edward C. Prescott. "Time to build and aggregate fluctuations." Econometrica: Journal of the Econometric Society (1982): 1345-1370.

- For the first time, macroeconomists had a small and coherent dynamic model of the economy, built from first principles with optimizing agents, rational expectations, and market clearing, that could generate data that resembled observed variables to a remarkable degree.
- There were many dimensions along which the model failed, from the volatility of hours to the persistence of output.
- But the amazing feature was how well the model did despite having so little of what was traditionally thought of as the necessary ingredients of business cycle theories: money, nominal rigidities, or non-market clearing.

# DSGE quick history, ctd.

- The initial reaction to Kydland and Prescott's assertions varied from incredulity to straightforward dismissal
- Reasons? Due to the main characteristics:
  - ► The efficiency of business cycles:
    - The bulk of economic fluctuations observed in industrialized countries could be interpreted as an equilibrium outcome resulting from the economy's response to exogenous variations in real forces in an environment with perfect competition and frictionless markets
  - Importance of technological shocks
    - Basic model able to generate "realistic" fluctuations in output and other macroeconomic variables
  - ► The limited role of monetary factors
    - Theory sought to explain economic fluctuations with no reference to monetary factors, even abstracting from the existence of a monetary sector
  - Technical complexity

# DSGE quick history, ctd.

- Nowadays, DSGE model—leveraging on the initial intuition of Kydland and Prescott's (1982) paper—are flexible enough to accommodate rigidities
  - Monopolistic competition: Without market power, any firm that does not immediately adjust its prices will lose all its sales; (Blanchard and Kiyotaki, 1987)
  - ▶ Nominal rigidities: firms are subject to constraints on the frequency with which they can adjust the prices of goods and services they sell (Calvo, 1983)
  - Short run non-neutrality of monetary policy: A monetary policy rule, such as a money growth process or a Taylor rule, is used as a monetary authority.

#### Reference:

Woodford, Michael. Interest and prices: Foundations of a theory of monetary policy. princeton university press, 2011.

- We will now introduce a simple DSGE model that does not have all the features that I have just enumerated
- This is for two reasons:
  - I need to keep the presentation of the material accessible—realistic models (Smets and Wouters, 2003) are too large to be used in a didactic setting
  - Fortunately, we do not loose much. In fact, considering a prototypical DSGE model will help us in highlighting the econometric issues that arise in a realistic settings without having to deal with theirs complications

$$E_t\left[g(\zeta_{t+1},\varepsilon_{t+1},\theta)\right] = \\ \int g(\zeta_{t+1},\varepsilon_{t+1},\theta)f(\zeta_{t+1},\varepsilon_{t+1},\theta|\zeta_t,\zeta_{t-1},z_t)d\zeta_{t+1}d\varepsilon_{t+1}$$

- u<sub>t</sub>: exogenous shock
- $\bullet \ \underline{\theta = (\beta, \lambda, \tau, \alpha, \delta, \rho, \sigma_u^2)}$

structural parameters

- Both welfare theorems hold in this economy.
- Thus, we can solve directly for the social planner's problem:

$$\begin{split} \max_{\{C_t, H_t\}} E_0 \sum_{t=1}^{\infty} \beta^{t-1} \frac{\left(C_t^{\lambda} (1 - H_t)^{1-\lambda}\right)^{1-\tau}}{1 - \tau} \\ \text{subject to} \\ C_t + I_t &= e^{z_t} K_t^{\alpha} H_t^{1-\alpha} \\ K_{t+1} &= I_t + (1 - \delta) K_t \\ z_t &= \rho z_{t-1} + \varepsilon_t, \ |\rho| < 1, \ \varepsilon_t \sim \textit{N}(0, \sigma_{\varepsilon}^2) \\ z_0, K_0 \end{split}$$

▶ maximize the utility of the household subject to the production function, the evolution of technology, the law of motion for capital, the resource constraint, and some initial  $k_0$  and  $z_0$ .

#### First Order Conditions

The model is fully characterized by the first order conditions:

$$\begin{split} 1 &= E_t \left[ \beta \left( \frac{C_{t+1}}{C_t} \right)^{\lambda(1-\tau)} \left( \frac{1 - H_{t+1}}{1 - H_t} \right)^{(1-\lambda)(1-\tau)} R_{t+1} \right] \\ R_{t+1} &\equiv (1 - \delta) + \alpha e^{z_{t+1}} K_{t+1}^{\alpha - 1} H_{t+1}^{1 - \alpha} \\ (1 - \lambda) \frac{1}{(1 - H_t)} &= \frac{\lambda (1 - \alpha) e^{z_t} K_t^{\alpha} H_t^{-\alpha}}{C_t} \\ C_t + K_{t+1} &= e^{z_t} K_t^{\alpha} H_t^{1 - \alpha} + (1 - \delta) K_t \\ z_t &= \rho z_{t-1} + \varepsilon_t. \end{split}$$

It "clearly" fits

$$E_t[f(\zeta_{t+1}, \varepsilon_{t+1}, \theta)] = 0$$

#### First order conditions

$$\begin{split} 1 &= E_t \left[ \beta \left( \frac{C_{t+1}}{C_t} \right)^{\lambda(1-\tau)} \left( \frac{1 - H_{t+1}}{1 - H_t} \right)^{(1-\lambda)(1-\tau)} R_{t+1} \right] \\ R_{t+1} &\equiv (1 - \delta) + \alpha e^{z_t + 1} K_{t+1}^{t-1} H_{t+1}^{1-\alpha} \\ (1 - \lambda) \frac{1}{(1 - H_t)} &= \frac{\lambda(1 - \alpha) e^{z_t} K_t^{\alpha} H_t^{-\alpha}}{C_t} \\ C_t + K_{t+1} &= e^{z_t} K_t^{\alpha} H_t^{1-\alpha} + (1 - \delta) K_t \\ z_t &= \rho z_{t-1} + \varepsilon_t. \end{split}$$

$$\implies R_{t+1} = f(z_{t+1}, K_{t+1}, H_{t+1}, v_t, \theta)$$

$$\implies K_{t+1} = h(v_t)$$

#### First order conditions

 $z_t = \rho z_{t-1} + \varepsilon_t$ .

$$\begin{split} 1 &= E_t \left[ \beta \left( \frac{C_{t+1}}{C_t} \right)^{\lambda(1-\tau)} \left( \frac{1 - H_{t+1}}{1 - H_t} \right)^{(1-\lambda)(1-\tau)} R_{t+1} \right] \\ & \iff R_{t+1} = (1 - \delta) + \alpha e^{z_{t+1}} K_{t+1}^{\alpha - 1} H_{t+1}^{1 - \alpha} \\ & (1 - \lambda) \frac{1}{(1 - H_t)} = \frac{\lambda(1 - \alpha) e^{z_t} K_t^{\alpha} H_t^{1 - \alpha}}{C_t} \\ & \iff K_{t+1} = h(\nu_t) \end{split}$$

$$C_t + K_{t+1} = e^{z_t} K_t^{\alpha} H_t^{1 - \alpha} + (1 - \delta) K_t$$

#### Stochastic Singularity

$$\begin{split} &1 = E_t \left[ \beta \left( \frac{C_{t+1}}{C_t} \right)^{\lambda(1-\tau)} \left( \frac{1-H_{t+1}}{1-H_t} \right)^{(1-\lambda)(1-\tau)} R_{t+1} \right] \\ &R_{t+1} \equiv (1-\delta) + \alpha e^{z_{t+1}} K_{t+1}^{\alpha-1} H_{t+1}^{1-\alpha} \\ &(1-\lambda) \frac{1}{(1-H_t)} = \frac{\lambda(1-\alpha)e^{z_t} K_t^{\alpha} H_t^{-\alpha}}{C_t} \\ &C_t + K_{t+1} = e^{z_t} K_t^{\alpha} H_t^{1-\alpha} + (1-\delta) K_t \\ &z_t = \rho z_{t-1} + \varepsilon_t. \end{split}$$

$$\begin{split} E_t[g(C_{t+1}, H_{t+1}, z_{t+1}, \theta)] &= 0 \\ z_{t+1} &= \rho z_t + \varepsilon_{t+1} \\ (1 - \lambda) \frac{1}{(1 - H_t)} &= e^{z_t} K_t^{\alpha} H_t^{1 - \alpha} + (1 - \delta) K_t \end{split}$$

Solution

## Policy function

The solution of the dynamic system is a decision rule

$$\underbrace{\zeta_t = r(\zeta_{t-1}, \varepsilon_t; heta)}_{ ext{policy function}}$$

- Policy function are not available in closed form (except for very stylized models)
- We often forced to resort to numerical approximations to characterize the equilibrium dynamics of the model
- Three "historical" approaches
  - ▶ using a linear quadratic approximation of the model (Kydland and Prescott, 1982)
  - value function iterations (Christiano, 1990)
  - ► (log-)linearization of equilibrium conditions (King, Plosser, Rebelo, 2002)

In this course we will focus on the last approach, since it is the one used in a

Solution: Linearization

- Non-stochastic steady state (NSSS)
- 2 Linearization
  - e.g.,

$$E[g(x_{t+1})] \approx E[g(\bar{x}) + g'(\bar{x})(x_{t+1} - 1)]$$

- Gensys' canonical form
- Analyze linear rational expectations systems and return solutions for their dependence on exogenous disturbances
- $\odot$  Estimate the parameter vector heta
- © Conduct policy experiments ->
  - what happens if there is a shock to interest rates?
  - a shock to technology?
  - what is the effect on the macroeconomy if government expenditure are increased?

Solution: Linearization

- Non-stochastic steady state (NSSS)
- 2 Linearization
  - e.g.,

$$E[g(x_{t+1})] \approx E[g(\bar{x}) + g'(\bar{x})(x_{t+1} - 1)]$$

- Gensys' canonical form
- Analyze linear rational expectations systems and return solutions for their dependence on exogenous disturbances
- $\odot$  Estimate the parameter vector heta
- © Conduct policy experiments ->
  - what happens if there is a shock to interest rates?
  - a shock to technology?
  - what is the effect on the macroeconomy if government expenditure are increased?

Solution: Linearization

- Non-stochastic steady state (NSSS)
- 2 Linearization
  - e.g.,

$$E[g(x_{t+1})] \approx E[g(\bar{x}) + g'(\bar{x})(x_{t+1} - 1)]$$

  - a shock to technology?
  - what is the effect on the macroeconomy if government expenditure are increased?

Solution: Linearization

- Non-stochastic steady state (NSSS)
- 2 Linearization
  - e.g.,

$$E[g(x_{t+1})] \approx E[g(\bar{x}) + g'(\bar{x})(x_{t+1} - 1)]$$

- Gensys' canonical form
- Analyze linear rational expectations systems and return solutions for their dependence on exogenous disturbances
- **5** Estimate the parameter vector  $\theta$
- Onduct policy experiments ->
  - what happens if there is a shock to interest rates?
  - a shock to technology?
  - what is the effect on the macroeconomy if government expenditure are increased?

Non-stochastic steady state

The NSSS of the model is found by

- **1** setting the shock to  $z_t = \bar{z} = 0$
- dropping the time indexes
- 3 solving for the endogenous variables.
  - This is usually just a matter of getting the algebra right!

#### Linearization

For the Neoclassical Growth Model, the NSSS is given:

$$K_{ss} = S_1/(S_2S_1 + S_3)$$
 (1)

$$H_{ss} = S_2 K_{ss} \tag{2}$$

$$C_{ss} = S_3 K_{ss} (3)$$

$$Y_{ss} = K_{ss}^{\alpha} H_{ss}^{1-\alpha}, \tag{4}$$

where

$$S_1 = rac{\lambda (1-lpha) S_2^{-lpha}}{(1-\lambda)}, \quad S_2 = rac{(1/eta - 1 + \delta))^{1/(1-lpha)}}{lpha}, \quad S_3 = (S_2^{1-lpha} - \delta).$$

Note: The NSSS is a function of the parameters

$$K_{ss} = K(\theta), \ H_{ss} = H(\theta), \ C_{ss} = C(\theta), \ Y_{ss} = Y(\theta)$$

#### Linearization

The linearization gives a set of linear equations that describe the model around the NSSS.

$$\Gamma_0(\theta)E[x_{t+1}] = \Gamma_1x_t(\theta) + C + \Psi(\theta)z_t$$

- The variables  $(x_t)$  are expressed in deviation from the NSSS
- $\Gamma_0(\theta)$ ,  $\Gamma_1(\theta)$ , and  $\Psi(\theta)$  are function of the structural parameter  $\theta$
- Several solution algorithms are available for this linear rational expectations system: e.g.,
  - Blanchard, Olivier Jean, and Charles M. Kahn. "The solution of linear difference models under rational expectations." Econometrica: Journal of the Econometric Society (1980): 1305-1311.
  - ► Sims, Christopher A. "Solving linear rational expectations models." Computational Economics 20.1 (2002): 1-20.
- All this different linear methods are equivalent, as the linear approximation of a differentiable function is unique and invariant (differentiable parameters transformations)

Linearization

For  $k_t = K_t - K_{ss}$  and  $h_t = H_t - H_{ss}$ , the linearized version of the model is

$$Ak_{t+1} + Bk_t + Ch_t + Dz_t = 0 (5)$$

$$E_t(Gk_{t+1} + Hk_t + Jh_{t+1} + Kh_t + Lz_{t+1} + Mz_t) = 0$$
 (6)

$$Ez_{t+1} = Nz_t, (7)$$

where the coefficient A, B, C, ..., N are functions of the structural parameter  $\theta$ .

Linearization, ctd.

Expression for the coefficient of the policy functions

$$A = 1$$

$$B = (\alpha/K_{ss})C_{ss} - Y_{ss}(\alpha/K_{ss}) - (1 - \delta)$$

$$C = -((\alpha/H_{ss}) + 1/(1 - H_{ss}))C_{ss} - Y_{ss}((1 - \alpha)/H_{ss})$$

$$D = C_{ss} - Y_{ss}$$

$$G = \alpha(\lambda(1 - \tau) - 1)/K_{ss}$$

$$H = (\lambda(1 - \tau) - 1)/K_{ss}$$

$$J = -\alpha(\lambda(1 - \tau) - 1)((\alpha/H_{ss}) + (1/(1 - H_{ss})))$$

$$+\beta(\alpha(1 - \alpha)/H_{ss})K_{ss}^{\alpha - 1}H_{ss}^{1 - \alpha} - ((1 - \tau)(1 - \lambda)/(1 - H_{ss}))$$

$$K = \alpha(\lambda(1 - \tau) - 1)((\alpha/H_{ss}) + (1/(1 - H_{ss}))) - (1 - \lambda)(1 - \tau)/(1 - H_{ss})$$

$$L = \lambda(1 - \tau) - H_{ss} + \alpha\beta K_{ss}^{\alpha - 1}H_{ss}^{1 - \alpha}$$

$$M = \lambda(1 - \tau) - H_{ss}$$

$$N = \rho$$

4 D > 4 B > 4 B > 4 B > 9 Q P

#### Solution

The solution of the system of rational expectation equation is given by:

$$k_{t+1} = P(\theta)k_t + Q(\theta)z_t$$

$$h_{t+1} = R(\theta)P(\theta)k_t + (R(\theta)Q(\theta) - S(\theta)\rho)z_t + S(\theta)\varepsilon_{t+1}$$

$$z_{t+1} = \rho z_t + \varepsilon_{t+1}.$$

We can thus write

$$x_{t+1} = G_0(\theta) + G(\theta)x_t + M(\theta)\varepsilon_{t+1}$$

where

$$x_{t+1} = \begin{bmatrix} k_{t+1} \\ h_{t+1} \\ z_{t+1} \end{bmatrix}, \quad G(\theta) = \begin{bmatrix} P(\theta) & 0 & Q(\theta) \\ R(\theta)P(\theta) & 0 & R(\theta)Q(\theta) - S(\theta)\rho \\ 0 & 0 & \rho \end{bmatrix}, \quad M(\theta)$$

The coefficients of the policy functions are:

$$P = \frac{1}{2} \left( \frac{GC}{JA} - \frac{B}{A} - \frac{K}{J} - \sqrt{\left( \frac{\frac{B}{A} + \frac{K}{J} - \frac{GC}{JA}}{JA} \right)^2} - 4 \frac{KB - HC}{JA} \right)$$

$$R = -\frac{1}{C} (APB)$$

$$Q = \frac{CLN - D(J + N + K)}{AJN + AK - CG - CJR}$$

$$S = \frac{DG + DJR - ALN - AM}{AJN + AK - CG - CJR}$$

#### State-space representation

The data enter through the specification of a set of measurement equations:

$$\underbrace{y_t}_{\text{observables}} = H(\theta)x_t\underbrace{\left(+m(\theta)\eta_t\right)}_{\text{meas. error}}$$

#### State-space representation

The reduced-form model is given by the following state-space form:

$$x_{t+1} = G_0(\theta) + G(\theta)x_t + M(\theta)\varepsilon_{t+1}$$
$$y_t = H(\theta)x_t (+m(\theta)\eta_{t+1})$$

#### State-space representation

The data enter through the specification of a set of measurement equations:

$$\underbrace{y_t}_{\text{observables}} = H(\theta)x_t\underbrace{(+m(\theta)\eta_t)}_{\text{meas. error}}$$
observation equation

#### State-space representation

The reduced-form model is given by the following state-space form:

$$x_{t+1} = G_0(\theta) + G(\theta)x_t + M(\theta)\varepsilon_{t+1}$$
$$y_t = H(\theta)x_t (+m(\theta)\eta_{t+1})$$

Solutions: Remarks

The "true" model is highly non-linear:

$$E_t[f(\zeta_{t+1}, \varepsilon_{t+1}, \theta)] = 0$$

• We end up with a linear model:

$$x_{t+1} = G_0(\theta) + G(\theta)x_t + M(\theta)\varepsilon_{t+1}$$
  
$$y_{t+1} = H(\theta)x_t(+m(\theta)\eta_t)$$

- linearization may have important implications
- ....but it simplifies estimation of the model

• The "true" model is highly non-linear:

$$E_t[f(\zeta_{t+1}, \varepsilon_{t+1}, \theta)] = 0$$

• We end up with a linear model:

$$x_{t+1} = G_0(\theta) + G(\theta)x_t + M(\theta)\varepsilon_{t+1}$$
  
$$y_{t+1} = H(\theta)x_t(+m(\theta)\eta_t)$$

- linearization may have important implications
- ....but it simplifies estimation of the model.

Solutions: Remarks

The "true" model is highly non-linear:

$$E_t[f(\zeta_{t+1}, \varepsilon_{t+1}, \theta)] = 0$$

We end up with a linear model:

$$x_{t+1} = G_0(\theta) + G(\theta)x_t + M(\theta)\varepsilon_{t+1}$$
  

$$y_{t+1} = H(\theta)x_t(+m(\theta)\eta_t)$$

- linearization may have important implications
- ....but it simplifies estimation of the model.

The "true" model is highly non-linear:

$$E_t[f(\zeta_{t+1}, \varepsilon_{t+1}, \theta)] = 0$$

We end up with a linear model:

$$x_{t+1} = G_0(\theta) + G(\theta)x_t + M(\theta)\varepsilon_{t+1}$$
  

$$y_{t+1} = H(\theta)x_t (+m(\theta)\eta_t)$$

- linearization may have important implications
- ....but it simplifies estimation of the model.

#### Estimation.....

Given the state space model:

$$x_{t+1} = G_0(\theta) + G(\theta)x_t + M(\theta)\varepsilon_{t+1}$$
  

$$y_t = H(\theta)x_t (+m(\theta)\eta_t)$$

and knowing  $\theta$ , the structural parameter vector, we can—using standard filtering techniques fit the model to the data and assess its goodness of fit

- This is the approach that we will explore next,
- ...but first let's focus on the "glorious" past

- $\bullet$  First attempt to estimate parameters of macroeconomic models where limited to subset of  $\theta$
- Consider the Euler conditions of the neoclassical growth model

$$1 = E_t \left[ \beta \left( \frac{C_{t+1}}{C_t} \right)^{\lambda(1-\tau)} \left( \frac{1 - H_{t+1}}{1 - H_t} \right)^{(1-\lambda)(1-\tau)} R_{t+1} \right]$$

ullet For simplicity let  $\lambda=1$ , so that it reduces to

$$1 = E_t \left[ \beta \left( \frac{C_{t+1}}{C_t} \right)^{-\alpha} R_{t+1} \right], \quad \alpha \equiv \tau - 1.$$

The objective is to estimate  $(\beta, \alpha)$ .

• Hansen and Singleton (1982) do that building on Hansen (1982) celebrated GMM paper.

- Notice that the expectation is conditional to the information available at time t
- By the law of iterated expectation

$$E_t \left[ \beta \left( \frac{C_{t+1}}{C_t} \right)^{-\alpha} R_{t+1} - 1 \right] = 0$$

implies

$$E\left[\left(\beta\left(\frac{C_{t+1}}{C_t}\right)^{-\alpha}R_{t+1}-1\right)z_t\right]=0,$$

for any vector of variables  $z_t$  that is known at time t.

• Having observation on consumption and interest rates we could estimate  $(\beta, \alpha)$  by solving the empirical moment equation

$$\frac{1}{T}\sum_{t=1}^{T}\left(\beta\left(\frac{C_{t+1}}{C_{t}}\right)^{-\alpha}R_{t+1}-1\right)z_{t}=0.$$

- Two cases:
  - $dim(z_t) = 2$ : the system is exactly identified and thus is reasonable that a solution exists
  - $dim(z_t) > 2$ : the system is overidentified, thus no solution exists
- Assume that  $dim(z_t) = m \ge 2$ .

Let

$$g(w_t, \theta) \equiv \left(\beta \left(\frac{C_t}{C_{t-1}}\right)^{-\alpha} R_t - 1\right) z_t,$$

where  $w_{t+1} = \{C_{t+1}, C_t, R_{t+1}\}$  and  $\theta = \{\beta, \alpha\}$ . The GMM estimator is given by

$$\hat{\theta}^{GMM} = \arg\min_{\theta \in \Theta} \left[ \underbrace{\frac{1}{T} \sum_{t=1}^{T} g(w_t, \theta)'}_{1 \times m} \right] \underbrace{\frac{\mathcal{W}}{m \times m}}_{m \times m} \left[ \underbrace{\frac{1}{T} \sum_{t=1}^{T} g(w_t, \theta)}_{m \times 1} \right],$$

where W is a positive definite matrix.

Let  $\theta_0$  denote the "true" parameters, that is,

$$E[g(w_t,\theta_0)]=0.$$

Under regularity conditions,

$$\hat{\theta} \stackrel{p}{\to} \theta_0$$

and

$$\sqrt{T}(\hat{\theta}-\theta_0) \xrightarrow{d} N(0,V_W)$$

- The GMM estimator is consistent regardless of the weighting matrix
- The GMM estimator is asymptotically normal with a variance that depends on the weighting matrix W,  $V_W$
- Which W should we use? ...the one that minimizes the asymptotic variance.....

The (optimal, efficient) GMM estimator is defined as

$$\hat{\theta}^{\textit{GMM}} = \arg\min_{\theta \in \Theta} \left[ \underbrace{\frac{1}{\mathcal{T}} \sum_{t=1}^{\mathcal{T}} g(w_t, \theta)'}_{1 \times m} \right] \underbrace{\Omega^{-1}}_{m \times m} \left[ \underbrace{\frac{1}{\mathcal{T}} \sum_{t=1}^{\mathcal{T}} g(w_t, \theta)}_{m \times 1} \right],$$

where

$$\Omega = E[g(w_t, \theta_0)g(w_t, \theta_0)'].$$

In this case,

$$\sqrt{T}(\hat{\theta}^{GMM} - \theta) \stackrel{d}{\rightarrow} N(0, V), \ V = (G'\Omega^{-1}G)^{-1}, \ G = E[\partial g(w_t, \theta_0)/\partial \theta_0]$$

• Hansen (1982) shows that  $V < V_W$ .

# Two-step procedures

- In practice  $\Omega$  is not know
- Can be estimated using a preliminary consistent estimator of  $\theta_0$ , say  $ilde{ heta} \stackrel{p}{\to} \theta_0$

$$\widehat{\Omega} = rac{1}{T} \sum_{t=1}^{T} g(w_t, \widetilde{ heta}) g(w_t, \widetilde{ heta})'$$

Then solve

$$\hat{\theta}^{GMM} = \arg\min_{\theta \in \Theta} \left[ \underbrace{\frac{1}{T} \sum_{t=1}^{T} g(w_t, \theta)'}_{1 \times m} \right] \underbrace{\widehat{\Omega}^{-1}}_{m \times m} \left[ \underbrace{\frac{1}{T} \sum_{t=1}^{T} g(w_t, \theta)}_{m \times 1} \right]$$

 $\bullet$  It is a two step procedures because  $\tilde{\theta}$  is a GMM with non-optimal weighting matrix

#### Test of overidentified restrictions

ullet If the model is correctly specified, that is, there exists a  $heta_0$  such that

$$E[g(w_t, \theta_0)] = 0,$$

then

$$J = T \left[ \underbrace{\frac{1}{T} \sum_{t=1}^{T} g(w_t, \hat{\theta}^{GMM})'}_{1 \times m} \right] \underbrace{\widehat{\Omega}^{-1}}_{m \times m} \left[ \underbrace{\frac{1}{T} \sum_{t=1}^{T} g(w_t, \hat{\theta}^{GMM})}_{m \times 1} \right] \xrightarrow{d} \chi^2_{m-k}$$

J statistics—as it is commonly referred to—can then be used to test
whether the model is correctly specified (but in reality we are testing
whether the over-identified restrictions are satisfied)

# Application to US economy

- ullet Per capita real consumption (non-durables plus services)  $C_t$
- ullet Real risk free rate  $r_t^{rf}$ ,  $R_t^{rf}=1+r_t^{rf}$
- Instruments

$$z_t^{(1)} = \begin{pmatrix} 1 \\ C_t/C_{t-1} \end{pmatrix}, \quad z_t^{(2)} = \begin{pmatrix} 1 \\ C_t/C_{t-1} \\ 1+\pi_t \end{pmatrix}$$

# US data

Objective value: 25.97 on 1 DF, p-value: 3.46e-07
```

Observations: 214, moment restrictions: 3

# Testing the model

• The *J* statistic is very large:

$$J = 25.97$$

• Since m-k=1 in this case, the critical value for a 5% significance test is 3.84

$$\Pr(\chi_1^2 > 3.84) \approx 0.05.$$

Since

we reject the null hypothesis the the over-identified conditions hold at the 5% significance level (actually we reject at any reasonable significance level)

# **GMM** critiques

- Small sample performances of GMM are often very poor
  - Special issues of Journal of Business and Economic Statistics: vol. 14, no. 3

# Continuous updating

The Continuous Updating GMM estimates minimizes the objective function over  $\theta_0$ 

$$\arg\min_{\theta\in\Theta}\left[\underbrace{\frac{1}{T}\sum_{t=1}^{T}g(w_t,\theta)'}_{1\times m}\right]\underbrace{\left[\frac{1}{T}\sum_{t=1}^{T}g(w_t,\theta)g(w_t,\theta)'\right]^{-1}}_{m\times m}\left[\underbrace{\frac{1}{T}\sum_{t=1}^{T}g(w_t,\theta)}_{m\times 1}\right]$$

- In Monte-Carlo experiments this method demonstrated a better performance than the traditional two-step GMM: the estimator has smaller median bias (although fatter tails), and the J-test for overidentifying restrictions in many cases was more reliable
- Implementation is somewhat more difficult.....
